ABSTRACT

We introduce MRMR, the first expert-level multidisciplinary multimodal retrieval benchmark requiring intensive reasoning. MRMR contains 1,502 queries spanning 23 domains, with positive documents carefully verified by human experts. Compared to prior benchmarks, MRMR introduces three key advancements. First, it challenges retrieval systems across diverse areas of expertise, enabling fine-grained model comparison across domains. Second, queries are reasoning-intensive, with images requiring deeper interpretation such as diagnosing microscopic slides. We further introduce Contradiction Retrieval, a novel task requiring models to identify conflicting concepts. Finally, queries and documents are constructed as image–text interleaved sequences. Unlike earlier benchmarks restricted to single images or unimodal documents, MRMR offers a realistic setting with multi-image queries and mixed-modality corpus documents. We conduct an extensive evaluation of 4 categories of multimodal retrieval systems and 14 frontier models on MRMR. The text embedding model Qwen3-Embedding with LLM-generated image captions achieves the highest performance, highlighting substantial room for improving multimodal retrieval models. Although latest multimodal models such as Ops-MM-Embedding perform competitively on expert-domain queries, they fall short on reasoning-intensive tasks. We believe that MRMR paves the way for advancing multimodal retrieval in more realistic and challenging scenarios.

1 INTRODUCTION

LLM-based agents, such as DeepResearch (OpenAI, 2024; Qiao et al., 2025), have been widely applied in domains including science, engineering, medicine, and finance (Zhao et al., 2025; Tang et al., 2024; Barry et al., 2025; Phan et al., 2025). These systems move beyond the intrinsic knowledge of LLMs by actively retrieving and integrating external information, making a strong and robust retrieval component essential (Chen et al., 2025). In practice, many expert-domain applications rely on multimodal information, underscoring the need for retrieval methods that can handle queries and documents spanning both visual and textual modalities, or even interleaved image–text content (Zhang et al., 2021; Liu et al., 2021; 2023). For instance, given a medical image, the agent system should retrieve similar cases or guidelines to support clinical decisions.

While existing multimodal retrieval benchmarks have made progress, they are insufficient to capture the complexity of agentic scenarios. We identify three key limitations: (1) **Multidisciplinary expert domains**: most multimodal benchmarks are built on Wikipedia text and images, focusing on general-domain knowledge (Hu et al., 2023; Chen et al., 2023; Zhang et al., 2025b). However, state-of-the-art LLMs already demonstrate strong capabilities in handling such knowledge (Team et al., 2025), making it essential to develop benchmarks for high-stakes expert domains such as medicine, science,

[*] Equal contribution.

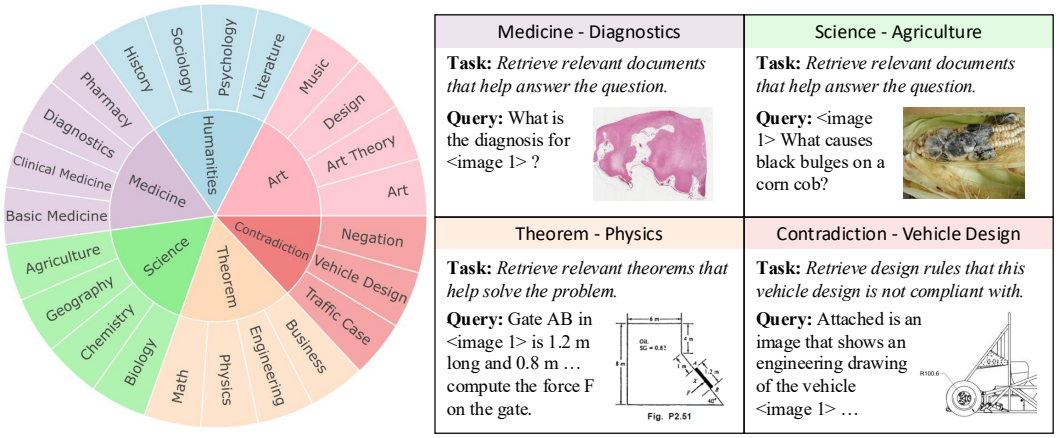

Figure 1: Overview of the MRMR benchmark. MRMR includes 1,502 expert-annotated examples, covering 23 domains across 6 disciplines. It is specifically designed to assess multimodal retrieval models in expert-level, reasoning-intensive tasks. Notably, we originally introduce the *Contradiction Retrieval* task in the multimodal setting, which requires retrieving documents that conflict with the user query and features deeper logical reasoning.

and engineering. (2) **Reasoning intensity**: existing benchmarks primarily target semantic matching and information-seeking tasks, whereas real-world queries often involve expert-domain images and require deeper understanding and logical reasoning over them. (3) **Image-text interleaving**: prior benchmarks mostly support single-image queries with supplementary text, yet real-world queries and documents typically consist of interleaved text and multiple images (Zhang et al., 2025b).

To address these gaps, we introduce **MRMR**, a comprehensive benchmark measuring retrieval models in expert-level **M**ultidisciplinary and **R**easoning-intensive **M**ultimodal **R**etrieval. Figure 1 presents an overview of our benchmark. MRMR consists of 1,502 expert-annotated examples, categorized into three types of retrieval tasks: (1) *Knowledge* for retrieving web pages related to queries involving multiple expert-domain images; (2) *Theorem* for retrieving theorems involved in solving multimodal math problems; and (3) *Contradiction* for retrieving contradictory statements or rules given a case description. Specifically, we derive complex multidisciplinary queries from established Visual Question Answering (VQA) benchmarks (Yue et al., 2024; 2025) and assign expert annotators to collect positive documents from Internet. To build a sizable corpus, we additionally include negative documents from knowledge-intensive collections (Wang et al., 2024a; Su et al., 2025). To further elevate the reasoning challenge, we originally introduce *Contradiction Retrieval*, which requires models not only to detect semantic relevance but also to perform logical reasoning to identify conflicting concepts. To foster a deeper integration of visual and textual content, we represent both queries and documents in an interleaved multimodal format.

We conduct an extensive evaluation on MRMR across four main categories of multimodal retrieval paradigms and 14 representative models. The results reveal that current multimodal retrieval systems consistently underperform text-only retrievers with image captioning on knowledge- and reasoning-intensive multimodal queries. The highest score of 52.1 nDCG@10 is achieved by the text embedding model Qwen3-Embedding (Zhang et al., 2025d) combined with LLM-based image captioning. The best-performing multimodal model, Ops-MM-Embedding (OpenSearch-AI, 2025), trails by 6.7 points, mainly due to its limited reasoning capabilities rather than domain expertise. Its performance drops from 67.4 on *Knowledge* tasks to 30.1 and 36.6 on *Theorem* and *Contradiction* tasks, even though the corpora for these two tasks are much smaller than that of *Knowledge*. More importantly, the multidisciplinary setup in MRMR reveals substantial performance differences across models and domains. For instance, Ops-MM-Embedding surpasses the second-best model, MM-Embed (Lin et al., 2025), in the Art discipline, whereas their performances are comparable in the Medicine discipline. We hope our benchmark and findings will help progress in multimodal retrieval.

Table 1: Comparison of multimodal retrieval benchmarks and MRMR. In the "Modality" column, "T $\rightarrow$ I" indicates retrieving image documents using a text query. The "#Domain" column reports the number of domains; "Open" denotes datasets built from Wikidata with general domains. The "Expert", "Reason", and "Interleaved" columns indicate whether expert knowledge is required, whether intensive reasoning is involved, and whether data are in the interleaved image-text format.

2 Related Work

Benchmarking multimodal retrieval. As illustrated in Table 1, existing multimodal retrieval datasets mainly focus on semantic matching or information-seeking tasks. Early semantic matching benchmarks are built from paired image–text data, where the text is semantically aligned with the image (Liu et al., 2023; Wu et al., 2024; Xiao et al., 2025; Jiang et al., 2025c), and the task is to retrieve the corresponding modality. Composed Image Retrieval (CIR) emerges as a challenging task that allows users to search for target images using a multimodal query, comprising a reference image and a modification text specifying the user's desired changes to the reference image (Zhang et al., 2021; Liu et al., 2021; Baldrati et al., 2023; Zhang et al., 2024). Information-seeking benchmarks either retrieve supporting evidence for visual questions (Hu et al., 2023; Chen et al., 2023) or retrieve multimodal documents for textual queries (Ma et al., 2024; Macé et al., 2025; Dong et al., 2025). As all prior studies focus on single-image inputs, TIIR (Zhang et al., 2025b) proposes a more realistic setup in which the query and document consist of interleaved text–image sequences supporting multiple images. However, it is limited to searching general-domain wikiHow tutorials. To further advance multimodal retrieval, we construct MRMR, the first benchmark comprising complex multidisciplinary queries that require in-depth reasoning in the interleaved text–image format.

Multimodal retrieval models and multimodal retrieval augmented generation. State-of-the-art multimodal retrieval models commonly rely on large pre-trained encoders such as CLIP (Radford et al., 2021) and BLIP (Li et al., 2023), which map images and texts into a shared embedding space. Their outputs are often combined using fusion strategies (*e.g.,* score fusion) to integrate information across modalities (Wei et al., 2024). More recent works adapt multimodal large language models (MLLMs) for universal multimodal embeddings by fine-tuning them on diverse retrieval tasks (Jiang et al., 2025b; Zhang et al., 2025c; Jiang et al., 2025c; Lin et al., 2025). In these approaches, multimodal queries are processed through the MLLM, and the hidden states from the final transformer layer, typically the last token representation, are used as the dense embedding for retrieval. In this work, we benchmark a diverse set of multimodal retrieval approaches, including text retrievers with image captioning, text and image two-stream models with vector fusion, and multimodal retrievers. Additionally, thanks to advances in both retriever and generative models, multimodal retrieval-augmented generation (MM-RAG) has emerged as a key application (Hu et al., 2025; Jiang et al., 2025a; Wu et al., 2025b; Zhan et al., 2025; Wasserman et al., 2025). While various MM-RAG benchmarks have been introduced, most focus on evaluating response generation and lack evidence-level relevance annotations, making it impractical to assess retrieval performance and its contribution within MM-RAG (Chen et al., 2025).

Table 2: Data statistics of MRMR. For each dataset, we show the number of queries (Q) and documents (D), the average number of positive documents (D_+) per example, the average number of text tokens of queries and documents (measured by the GPT-2 tokenizer (Radford et al., 2019), not including task instruction text), the average number of images in queries and documents, and sources of queries and documents. *Knowledge* datasets share a common retrieval corpus, while *Theorem* datasets share another. Examples for each dataset can be found in Appendix G.

Reasoning-intensive retrieval. Beyond keyword- and semantic-based information retrieval, BRIGHT (Su et al., 2025) has introduced the first benchmark in the text domain that requires intensive reasoning to identify relevant documents. For example, given a new math or physics problem, the retrieval system is expected to provide previously solved problems using the same theorems or relevant theorem statements. To tackle this challenge, recent methods train the text retrievers using synthetic datasets containing complex queries and hard negatives (Weller et al., 2025; Das et al., 2025; Zhang et al., 2025a; Long et al., 2025; Shao et al., 2025; FlagEmbedding, 2025). Our work extends reasoning-intensive retrieval into the multimodal domain. MRMR is constructed by sourcing expert-level queries from the multimodal understanding and reasoning benchmark MMMU (Yue et al., 2024), collecting image-text interleaved documents from web pages, and obtaining relevance annotations from human experts.

3 MRMR BENCHMARK

3.1 TASK FORMULATION

We define the task of multimodal retrieval as follows. Let $Q = \{q_1, \ldots, q_n\}$ be the set of queries and $D = \{d_1, \ldots, d_m\}$ the document corpus. Each query q and document d is represented as a sequence of segments $(x_1, \ldots, x_k)$, where each segment x can be either text or an image. For a query q, a document can be either a positive document d_+ (relevant) or a negative document d_- (non-relevant). In reasoning-intensive retrieval, a document d is considered relevant if it provides principles or theorems that support the reasoning chain required to answer query q (Su et al., 2025). Unlike prior studies (Xiao et al., 2025; Dong et al., 2025), we do not constrain the corpus to uniform data types, reflecting more realistic retrieval scenarios. To evaluate diverse reasoning capabilities, we design three types of retrieval tasks in MRMR:

- ***Knowledge*.** It emphasizes reasoning over broad expert domain knowledge. For a multimodal query, a document is relevant if expert annotators confirm that it contributes to reasoning about the query by providing critical concepts or theoretical foundations.
- ***Theorem*.** It targets the theorem-based reasoning over calculation problems. For a multimodal calculation query, a document is relevant if it conveys the same underlying theorem or formula needed to solve the problem.

- ***Contradiction*.** It requires logical reasoning to detect conflicting or inconsistent concepts. For a multimodal case description query, a document is relevant if it provides the rule or requirement that the query violates.

3.2 KNOWLEDGE: RETRIEVING WEB PAGES THAT HELP ANSWER QUESTIONS

MMMU (Yue et al., 2024) is one of the most widely used benchmark for evaluating multi-discipline multimodal understanding in MLLMs. Its robust version, MMMU-Pro (Yue et al., 2025), excludes questions solvable by text-only models, expands the candidate options, and provides verified correct answers. We repurpose the knowledge- and reasoning-intensive questions in MMMU-Pro as queries Q and construct a corpus D of image–text interleaved documents. The positive documents D_+ are scraped from relevant websites referenced by the GPT-Search[1] model (OpenAI, 2024) and verified by human experts; while negative documents D_- are augmented by sampling from the multimodal collection PIN-14M (Wang et al., 2024a) (see Figure 2).

Selecting questions. We prompt GPT-5[2] to categorize MMMU-Pro questions into two groups, *i.e.,* knowledge-based and calculation questions. We adopt calculation questions for the *Theorem* subset in Section 3.3. For knowledge questions, we then instruct GPT-5 to filter out questions that require only superficial reasoning over text and images, without reliance on external domain expertise. For the remaining questions, we generate detailed descriptions for each associated image using GPT-5, which we include as part of the input context for subsequent steps.

Constructing positive and hard negative documents. Unlike keyword- or semantic-based multimodal retrieval benchmarks, collecting positive documents for our queries is more time-consuming because it requires identifying and validating multimodal sources that support the query's answer. To address this, we design a semi-automated pipeline with human expert annotators. Specifically, for each query, given the GPT-5-generated image descriptions and ground-truth answer, we prompt GPT-Search to reason over the question and generate an explanation for the correct answer with reference web links pointing to diverse materials such as Wikipedia, books, academic papers, and blogs. To preserve the completeness of multimodal content, we capture these webpages as PDFs, apply MonkeyOCR (Li et al., 2025) to extract interleaved text and images, and split the content into chunks while preserving image references. Resulting documents are then screened by GPT-5 and validated by human experts about whether they support the correct answer. Documents with GPT-human agreement on relevance are retained as positives, those agreed irrelevant as hard negatives, while ambiguous cases (30–60% across domains) are discarded. In cases where GPT-Search fails to retrieve relevant documents (38.2% of questions), expert annotators are instructed to search the web and create one supporting document, optionally including image links within the text. Due to the complexity of the questions, the number of positive documents per query is typically fewer than four. We annotate data anonymously through the Turkle platform (HLT-COE@JHU, 2025), with detailed guidelines provided in Appendix B.

Constructing additional negative documents. After the previous step, we obtain 993 cleaned and annotated documents for 555 queries. To construct a sizable retrieval corpus comparable to (Xiao et al., 2025; Su et al., 2025), we supplement these with negative documents sampled from the large-scale multimodal collection PIN-14M (Wang et al., 2024a), which contains knowledge-intensive resources such as medical articles from PubMed Central (PMC)[3] and web content from OBELICS (Laurençon et al., 2023). Given the wide topic coverage and large number of documents in PIN-14M, we assume a low probability of false negatives for our sampled documents. We validate this assumption through manual error analysis in Section 5.1. In total, we curate a corpus of 26,223 documents, including text only, image only, and text-image interleaved.[4]

[1] GPT-Search refers to the version `gpt-4o-search-preview-2025-03-11` throughout this work.

[2] GPT-5 refers to the version `gpt-5-2025-08-07` throughout this work.

[3] https://www.ncbi.nlm.nih.gov/pmc/

[4] The corpus could be further expanded by sampling additional expert-domain documents, which naturally increases retrieval difficulty and the probability of false negatives. We leave it as future work.

Figure 2: An overview of the data construction workflow for MRMR (*Knowledge*). We select and convert knowledge- and reasoning-intensive questions from MMMU-Pro (Yue et al., 2025) into retrieval queries. Web pages such as Wikipedia, blogs, and papers referenced by the GPT-Search model during reasoning are processed into documents through screen capturing, OCR (Li et al., 2025), and chunking. The relevance of resulting documents is first evaluated by GPT and then verified by expert annotators. Lastly, we source negative documents from the knowledge-intensive multimodal collection PIN-14M (Wang et al., 2024a) to construct a sizable corpus.

3.3 THEOREM: RETRIEVING RELEVANT THEOREMS THAT SOLVE PROBLEMS

As introduced by Su et al. (2025), retrieving relevant theorem statements can assist users in solving new math or physics problems. We extend this formulation to the multimodal domain by leveraging challenging calculation problems from MMMU-Pro. In this setting, the query q is a image-centric calculation problem, and the corpus D consists of theorem descriptions across domains such as mathematics, physics, engineering, and business. A document d is regarded as positive if it describes a theorem applicable to solving the query problem.

Selecting questions. From the calculation questions in MMMU-Pro, we first use GPT-5 to exclude questions that explicitly state the required theorem in the text. The remaining questions are then organized into four major domains: Math, Physics, Engineering, and Business. The Engineering domain further includes areas such as Mechanical Engineering, Computer Science, and Electronics, while the Business domain covers Finance, Economics, Marketing, and related fields. Then, we prompt GPT-5 to reason through each multimodal question, produce a final answer, and summarize the key theorems used in the solution. We exclude questions for which GPT-5 produces incorrect answers, with a final set of 579 questions.

Constructing positive and negative documents. We adopt the theorem statements from BRIGHT (Su et al., 2025) as the primary retrieval corpus (∼13.8k documents), reflecting the realistic setting where most theorems are expressed in text. For each question, the summarized key theorems are used as queries to retrieve the top-10 candidate statements from the corpus with the Qwen3-Embedding model (Zhang et al., 2025d). Among these candidates, GPT-5 identifies the most relevant theorem statements, which are retained as positive documents, while the rest serve as negatives.

Constructing additional positive documents. Not all theorems have relevant counterparts in BRIGHT. To address this, we scrape additional theorem statements, optionally accompanied by illustrative images, from webpages such as Wikipedia, following the OCR pipeline described in Section 3.2. GPT-5 then rewrites these theorems to match the format of BRIGHT statements. Finally, we deduplicate the scraped documents to ensure a consistent and complete retrieval corpus. Consequently, 63.6% of the positive documents are sourced from webpages, with the remainder drawn from the BRIGHT corpus. More details are presented in Appendix C.

3.4 CONTRADICTION: RETRIEVING CONTRADICTORY RULES AND REQUIREMENTS

Most existing datasets emphasize retrieving positively supporting evidence for a query (Xiao et al., 2025; Chen et al., 2023; Dong et al., 2025). However, retrieving contradictory information could be of great importance especially in expert domains. For example, a user may provide a case description

and seek evidence of violation of laws, policies, or guidelines, as shown in Figure 19. In this setting, the query q is a case description (*e.g.,* traffic or vehicle design cases), while the corpus D comprises mandated rules (*e.g.,* driving theory handbooks or design requirements). A document d is considered positive if it contains the statement or rule contradicting the query case. Unlike traditional retrieval tasks, this new formulation requires not only semantic matching between query and document but also deep logical reasoning to identify conflicting concepts.

Negation. To study contradiction retrieval, we first design a synthetic task inspired by the negation benchmark NegBench (Alhamoud et al., 2025). Given an image from COCO (Lin et al., 2014) with ground truth object annotations, we synthesize four candidate text descriptions: three accurately reflecting the objects and one containing a contradiction, either by asserting the existence of a non-existent object or the absence of an existent one. Multimodal retrievers are evaluated on their ability to pinpoint the text description with contradiction relative to the given image. For example, in Figure 17, the query image shows a keyboard on the table, while the positive document explicitly states that none is present, revealing a contradiction. More details are provided in Appendix D.1.

Vehicle Design. To evaluate contradiction retrieval in engineering documents, we construct a vehicle design task by leveraging the Formula SAE Rulebook and design cases from the DesignQA dataset (Doris et al., 2025). In industrial product design, designers must review hundreds of pages of requirement documents to ensure their designs comply with specifications. To assist designers, retrieval systems are expected to identify the specific sections that a design case fails to satisfy. For example, in Figure 18, the vehicle's wheelbase in the design is shorter than the required minimum, indicating a contradiction. During data preparation, we introduce variations to the design cases and chunk the lengthy design document, as detailed in Appendix D.2.

Traffic Case. Retrieval systems have been applied to legal documents to assist legal professionals in preparing arguments and citations (Feng et al., 2024). To evaluate this capability in multimodality, we construct a traffic case task to assess whether retrievers can identify which driving rules are violated in traffic cases. We build the corpus by chunking official driving handbooks (Singapore Police Force, 2017) into sections. Meanwhile, we build the query set by selecting dozens of driving rules, each linked to several annotated violation cases. We augment these violation cases by replacing key textual elements with AI-generated images using Qwen-Image (Wu et al., 2025a). For example, as shown in Figure 19, a car is driving only 3 meters behind the vehicle ahead — significantly less than the required safe distance. Further details are provided in Appendix D.3.

4 Experiments

4.1 Experimental setup

We evaluate 4 types of multimodal retrieval setups with 14 frontier models, as follows: (1) **Text models with image caption (T2T)**: We assess text retrievers, namely BGE-M3 (Chen et al., 2024), NE-Embed-V2 (Lee et al., 2025), and Qwen3-Embedding-8B (Zhang et al., 2025d), by pairing with MLLM-generated image captions (see Appendix E.1 for details). (2) **Text and image two-stream models with vector fusion (IT2IT)**: We evaluate CLIP-style two-stream models, including EVA-CLIP (Sun et al., 2023), SigLIP (Zhai et al., 2023), OpenCLIP (Cherti et al., 2023), and JinaCLIP (Koukounas et al., 2024), by a simple vector-fusion strategy. Given an input sequence, we concatenate all text chunks for one text embedding t, while all images are concatenated vertically for another image embedding i. Following MTEB (Xiao et al., 2025), the final score is computed using the fused embedding $e = t + i$. (3) **Multimodal models with merged image (IT2IT)**: We evaluate multimodal retrievers including VISTA (Zhou et al., 2024), E5-V (Jiang et al., 2025b), MM-Embed (Lin et al., 2025), VLM2Vec (Jiang et al., 2025c), Ops-MM-Embedding (OpenSearch-AI, 2025) and GME-Qwen2-VL (Zhang et al., 2025c). Since these models support only single-image input, multiple images are concatenated in the same way as for two-stream models. (4) **Multimodal models with document as image (T2I)**: We also include the document retrieval paradigm that receives text-only query and encode entire multimodal documents as screenshot images, such as ColPali (Faysse et al., 2025). Because these models are trained for text queries, query images are replaced with LLM-generated captions, similar to the text retriever setup. Besides, we note that a native image–text interleaved model, TIIR (Zhang et al., 2025b), has been introduced and is expected to

Table 3: The performance of retrieval models on MRMR. We report nDCG@10 for all subtasks except Negation, for which we use Hit@1: Art, Medicine (Med.), Science (Sci.), Humanities (Hum.), Math, Physics (Phy.), Engineering (Eng.), Business (Bus.), Negation (Neg.), Design, and Traffic. Avg. denotes the average score across 11 subtasks. The best score on each subtask is highlighted in **bold**, and the second best is underlined.

best fit the interleaved format of MRMR; however, it is not publicly available. We provide details of each model in Appendix E.1. Following prior work (Xiao et al., 2025; Su et al., 2025), we use nDCG@10 as the main evaluation metric except Negation. Since each query in Negation has exactly one gold document among four candidates, we adopt Hit@1 as the main metric for this task.

4.2 Main Results

Multimodal retrieval systems lag behind text retrieval-based approaches on knowledge- and reasoning-intensive images. As shown in Table 3, the text retriever Qwen3-Embedding combined with LLM-based image captioning achieves the highest performance (52.1 nDCG@10). Although captions may omit certain visual details, they provide rich contextual descriptions and additional knowledge that substantially benefit retrieval. In contrast, multimodal systems struggle with the expert-level query images in MRMR, which often require deep reasoning, such as diagnosing microscopic tissue sections (Figure 1). CLIP-style two-stream models are particularly limited, as their training emphasizes alignment of superficial text–image semantics and model sizes are relatively small. The most recent MLLM-based embedding models, such as Ops-MM-Embedding, show promising results under both interleaved text–image and document-as-image paradigms, indicating the effectiveness of unified training on diverse retrieval tasks.

Multimodal retrieval systems perform particularly poorly on reasoning-intensive tasks. While Ops-MM-Embedding achieves a solid 67.4 nDCG@10 on *Knowledge* subtasks, its performance drops sharply to 30.1 and 36.6 on *Theorem* and *Contradiction*, respectively. Models such as E5-V and VLM2Vec perform even worse, essentially failing on these tasks. This gap highlights the difficulty of extracting abstract concepts from practical problems, for example linking an image-based physics question to the relevant theorem in Figure 1. Notably, Hit@1 scores for all models on the synthetic *Contradiction* task Negation remain below 25%—equivalent to random guessing given four candidates per query. As illustrated in the Negation example Figure 17, humans can readily detect conflicting concepts embedded within supporting evidence, yet retrieval models struggle even for strong text embedding models. Although the candidate corpora for the Design and Traffic sub-

tasks are much smaller than those of standard knowledge bases (Su et al., 2025; Dong et al., 2025), models still struggle to identify the underlying contradictions. Nevertheless, surface-level semantic matching remains useful in these settings, as it allows models to locate relevant documents without fully resolving the conflicting concepts (*e.g.,* a query concerning driving speed matched with a document specifying the speed limit). These findings suggest that current retrieval models possess strong capabilities in semantic matching and information seeking, but remain fundamentally limited in their reasoning ability.

Substantial differences in performance are evident across models and domains. Across all four multimodal retrieval settings, we observe a wide performance difference between models. For instance, among multimodal models with merged image, the weakest model, E5-V, achieves only 8.2 nDCG@10, whereas Ops-MM-Embedding reaches 45.4 nDCG@10, revealing substantial methodological differences. As MRMR is the first multidisciplinary multimodal retrieval benchmark, it enables fine-grained domain-level evaluation. For example, as shown in the breakdown performance Table 7, MM-Embed performs competitively with Ops-MM-Embedding in medical domains such as Clinical Medicine and Diagnostics, yet lags behind in art-related tasks. We also observe pronounced variation in retrieval difficulty across domains. In the Art subtasks, systems can often succeed by matching query images to visually identical or similar artworks, which narrows the search space. However, in medical imaging, such overlap is rare, and models are required to identify underlying pathological and radiological features rather than relying on superficial visual similarity.

5 Analysis

5.1 Qualitative analysis

To examine model limitations, we conduct 20 error case studies, each using the top-5 documents retrieved by Ops-MM-Embedding. We have observed two major failure patterns. (1) **Visual bias over contextual relevance**: in the Agriculture case (Appendix F Figure 7), the model ranks a negative document higher because it contains a nematode SEM image resembling the earthworm image in the query, even though the positive document provides a detailed discussion of the key topic Fauna. Similar errors occur in Medicine, where visually similar eye images from different diseases mislead the model. (2) **Failure of higher-level deduction**: in the Traffic case (Appendix F Figure 8), the model assigns a higher score to a negative document than to a positive one because both depict cars, tunnels, and lane markings. However, it fails to infer that the car is crossing the line, which contradicts the positive document's instruction to "Stay in lane". Although multimodal retrievers exhibit these shortcomings and lag behind text-only retrievers with image captions, we believe they remain essential because many real-world queries inherently span across modalities. Fundamentally, textual descriptions alone cannot fully capture the nuanced information in images, especially when MLLMs lack the required visual knowledge.

5.2 Test-time scaling in retrieval

Query expansion is a widely used technique, recently framed as test-time scaling in retrieval (Shao et al., 2025). Prior work (Su et al., 2025) demonstrates that incorporating explicit reasoning substantially improves performance on reasoning-intensive text retrieval tasks. Motivated by this, we have conducted comparative experiments to evaluate the effectiveness for multimodal retrieval. Specifically, we prompt MLLMs, including Qwen2-VL-2B-Instruct (Wang et al., 2024b) and Qwen2.5-VL-72B-Instruct (Bai et al., 2025), to generate reasoning traces, including question summarization and chain-of-thought reasoning, following (Su et al., 2025). As shown in Table 8, replacing the original queries with MLLM-generated reasoning traces leads to substantial performance improvements: $+16.5$ for Qwen2-VL-2B and $+26.5$ for Qwen2.5-VL-72B. The improvements are particularly pronounced on *Knowledge* tasks, whereas *Theorem* tasks benefit to a lesser extent. Meanwhile, we observe that, without constraining output length, the larger model Qwen2.5-VL-72B produces on average 20% and 60% more tokens than Qwen2-VL-2B in *Knowledge* and *Theorem* respectively, trading higher inference cost for larger performance gains.

6 Conclusion

We introduce MRMR, a realistic, multidisciplinary, reasoning-intensive multimodal retrieval benchmark. We leverage knowledge- and reasoning-intensive questions from MMMU-Pro and build a sizable multimodal corpus with positive documents verified by human experts. In addition, we introduce Contradiction Retrieval for evaluating models' logical reasoning capabilities to identify conflicts. Comprehensive evaluation shows that multimodal retrieval systems lag behind their text-retrieval counterparts, indicating substantial room for improvement. Although state-of-the-art multimodal models excel in *Knowledge* domains, they drop nearly 30 points on reasoning-intensive tasks. We hope MRMR facilitates identifying model limitations and advancing multimodal retrieval.

Code of Ethics and Ethics Statement

All data used in constructing MRMR are sourced from publicly available materials and are employed solely for academic research, not commercial use. We have carefully ensured that the dataset contains no private information or harmful content, such as discriminatory, violent, or unethical material. Our goal is to support socially beneficial research, and MRMR is released for unrestricted academic use. All experiments and data adhere to high scientific standards, ensuring accuracy, transparency, and reproducibility. For test-time scaling, we primarily focus on text expansion rather than image resizing and process as the text expansion has shown more significant impacts.

Reproducibility

Our datasets and annotation process are introduced in Section 3, and the experimental settings are described in Section 4. Specific implementation details can be found in Appendix E.1. To facilitate the reproduction of our experiments, the data is provided at https://huggingface.co/datasets/MRMRbenchmark.

A The Use of Large Language Models (LLMs)

In this work, large language models (LLMs) are employed solely as tools for data generation, as described in the main paper. Importantly, no parts of the manuscript are generated by LLMs. Hence, there are no concerns of plagiarism or scientific misconduct related to text generation.

B Dataset Construction: Knowledge

B.1 Annotator Biography

The detailed biographies of the annotators involved in MRMR construction are presented in **Table 4**. All annotators are from universities ranked in the Top 500 of the 2025 QS Global Rankings[3] and are fluent in English. Annotators assess document–query relevance by judging whether a document facilitates answering the query. To ensure quality, independent validators conduct an additional round of verification.

Table 4: Biographies of 24 annotators involved in MRMR construction (Author biographies are hidden to protect identity confidentiality).

ID	Year	Major	Assigned Subject(s)	Author?	Validator?
1	3rd year Undergraduate	Biological Engineering	Biology	✗	✗

B.2 Annotation Guideline and Interface

To facilitate data annotation, we develop the following interface based on Turkle (HLT-COE@JHU, 2025), an open-source clone of Amazon's Mechanical Turk. The annotation guideline and interface is detailed in Figure 3, Figure 4, and Figure 5.

B.3 Data Annotation Payment

The annotation and validation process for MRMR spanned three months. Each annotator was assigned approximately **50 questions** aligned with their academic major. After annotation, validators independently assessed the quality of the labels. We provided a *base rate* of **7 USD per hour**, with a quality adjustment of about 10%. On average, annotating a single question required **10 minutes**, while validation took **4 minutes**. This compensation scheme ensured that annotators received wages competitive with the average teaching assistant salary at their universities. To maintain a manageable workload and reduce pressure, we recommended a maximum of **10 questions per day**.

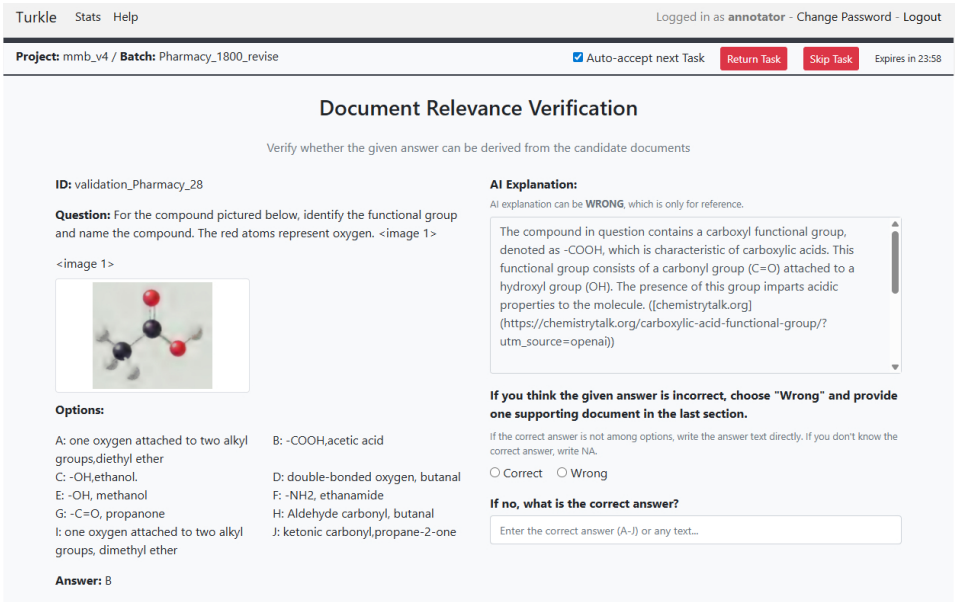

Figure 3: **Annotation Interface - Step 1: Question Understanding.** Annotators are first shown the question, associated images, candidate options, the correct answer, and an AI-generated explanation. The explanation is provided to aid understanding, though annotators are informed it may be incorrect. In this step, they judge whether the given answer is correct based on their own knowledge.

C Dataset Construction: Theorem

C.1 Theorem Database Construction

The BRIGHT theorem corpus was embedded using Qwen3-Embedding (Zhang et al., 2025d) and indexed in ChromaDB, which supports efficient semantic search via HNSW (Chroma, 2025). Each entry retains a unique `theorem_id` and the original `text`, enabling fast, semantics-aware retrieval with full traceability to the source.

C.2 Wikipedia Content Processing Pipeline

We retrieved Wikipedia content by querying the MediaWiki Search API (MediaWiki, 2024) using theorem names as search keys. For supplementary sources in PDF format, we employed MonkeyOCR (Li et al., 2025) to convert scanned documents into Markdown. The resulting text was then processed through a structured extraction prompt (Figure 6) using GPT-5 to perform final cleaning, normalization, and precise theorem statement extraction.

C.3 Deduplication Methodology

All theorems extracted from Wikipedia were deduplicated prior to inclusion in the corpus. Deduplication was performed in two stages: first by theorem name, and then by semantic content using TF-IDF–based cosine similarity (Salton & Buckley, 1988). Specifically, we employed `TfidfVectorizer` to compute `TF-IDF` vectors for all theorem statements (Pedregosa et al., 2011), followed by pairwise cosine similarity. Entries with near-identical content (cosine similarity ≥ 0.85) were collapsed into a single representative instance.

C.4 Quality Control and Validation

We ensured corpus quality through automated deduplication as mentioned in Section C.3, manual spot-checking of 20% of newly added Wikipedia content by domain experts, and robust error handling for failed downloads or OCR issues.

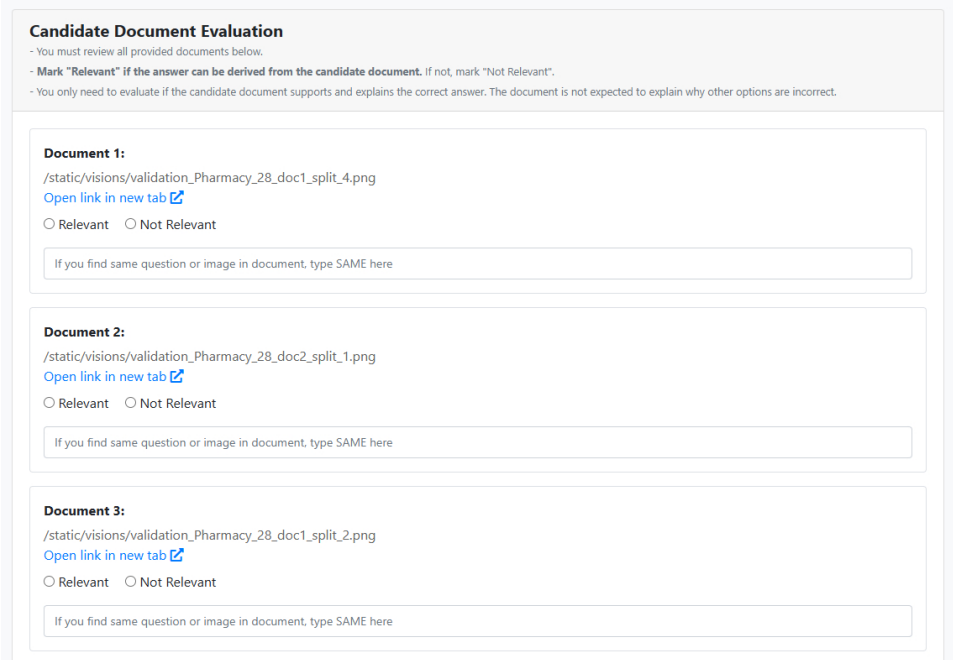

Figure 4: **Annotation Interface — Step 2: Candidate Document Evaluation.** After understanding the question, annotators are instructed to review candidate documents individually and judge whether each can facilitate correctly answering the question. Documents are shown in image format, with up to eight candidates presented. Document relevance definition has been explained to annotators before the annotation process.

D Dataset Construction: Contradiction

D.1 Negation

First, we randomly select 200 samples from the COCO (Lin et al., 2014) dataset, each containing at least three positive objectives. For each entry, we construct a description using the template, "The image includes a, b, c, but no d." In the positive description, we randomly select three positive objectives to replace a, b, and c, and select one negative objective to replace d. For the negative description, we generate two variations: one where all four objectives (a, b, c, d) are selected from the positive objectives, and another where one of a, b, or c is replaced by a randomly selected negative objective. The image from each sample is used as the query, and the three positive descriptions and one negative description are used as the corpus. Finally, we manually review the 200 queries and corresponding gold documents to ensure that the contradictory descriptions are identifiable by humans, and revise any ambiguous queries for clarity.

D.2 Vehicle Design

On one hand, to construct the queries, we use design cases from the DesignQA dataset (Doris et al., 2025) and augment them through appropriate modifications, such as altering numerical values and introducing variations in image elements. On the other hand, to construct the corpus, we apply MonkeyOCR (Li et al., 2025) to extract and segment the Formula SAE Rulebook into 700 files, organized by rule ID. Finally, we review all the queries to ensure they represent incorrect designs.

D.3 Traffic Case

First, we select a set of traffic rules and, based on these rules, create traffic violation cases by crafting relevant stories. These stories are then used as prompts to generate 12 images per story using GPT-5. Afterwards, we manually review all the generated images and use Doubao (Gong et al., 2025)

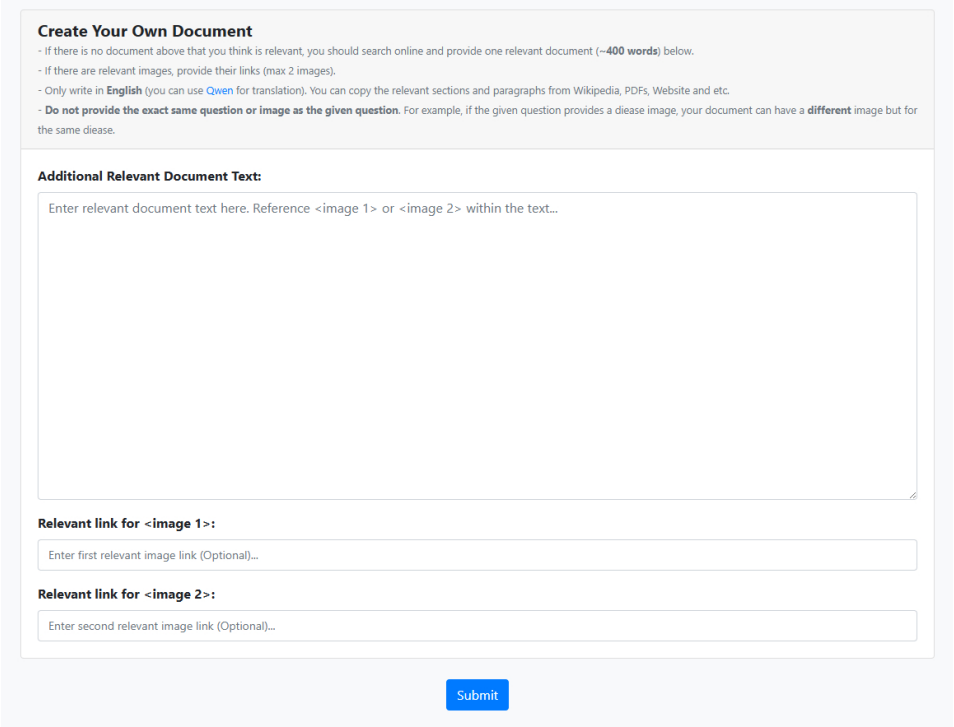

Figure 5: **Annotation Interface — Step 3: Create Relevant Document.** If none of the candidate documents are deemed relevant, annotators are required to search for a suitable web page and provide the gold evidence content. They are encouraged to include images from the source, and the final document is written in an interleaved image–text format.

You are given a markdown document. Your task is to extract the specific theorem, formula, equation, algorithm, or concept named "`{theorem_name}`" from this document.
Instructions:

1. Carefully locate the section that describes the theorem "`{theorem_name}`".
2. Extract the complete definition, explanation, and any associated formulas or equations.
3. Remove all reference citations.
4. If there are referenced images in the content, preserve the image references exactly as they appear.
5. Your response MUST follow the following LaTeX-style format:

```
\begin{definition}[{theorem_name}]
Complete definition and explanation,
preserving mathematical notation.
Include examples if present.
\end{definition}
```

Here is the document content:
`{markdown_content}`

Figure 6: GPT-5 prompt for cleaning the theorem content.

to refine and enhance them for better clarity and relevance. Additionally, we leverage Doubao to generate specific objectives from the queries in order to construct image–text interleaved queries. For the corpus, we use MonkeyOCR to split Basic Theory of Driving and Final Theory of Driving

(Singapore Police Force, 2017), two official driving handbooks in Singapore, into separate files, which are then organized and used as the corpus. Finally, we conduct a manual review of all the queries, ensuring that any additional corpus IDs caused by excessive image details are properly incorporated into the queries.

E Experiment Details

E.1 Models and Instructions

Table 5: Details of the multimodal retriever models evaluated in MRMR.

Model	Size	Version

MM-Embed (Lin et al., 2025)	8B	nvidia/MM-Embed
ColPali (Faysse et al., 2025)	3B	vidore/colpali-v1.3

Following TIIR, we evaluate text retrievers on multimodal retrieval tasks by replacing images with captions generated by an LLM. To simulate real-time inference, we apply the standardized prompt "Describe the image" and use Qwen2-VL-2B-Instruct to produce the captions.

Table 6: Instruction prompts used during model evaluation in MRMR.

Task	Modality	Prompt
Knowledge	Multimodal	Retrieve relevant documents that help answer the question.
	Text	
Theorem	Multimodal	Retrieve relevant theorems that are involved in solving the problem.
	Text	
Negation	Multimodal	Given an image, retrieve descriptions that have contradictory information with the image.
	Text	Given an image caption, retrieve descriptions that have contradictory information with the image caption.
Vehicle Design	Multimodal	Given a vehicle design, retrieve the design requirements that it violates.
	Text	Given a vehicle design description, retrieve the design requirements that it violates.
Traffic Case	Multimodal	Given a traffic case, retrieve the driving rule documents that it violates.
	Text	Given a traffic case description, retrieve the driving rule documents that it violates.

E.2 Implementations and Machines

The MRMR dataset is constructed following the conventions of MTEB (Muennighoff et al., 2023), including data format and evaluation pipeline, with modifications to support mixed-modality inputs during evaluation. All experiments are conducted on NVIDIA A100, A6000, or H100 GPUs. The runtime of a full evaluation depends on the model, but with the limited corpus size for efficiency, one complete run can be completed within 4 hours on a single A100 GPU for open-source dense models. To further accelerate dense model evaluation, we employ FlashAttention (Dao et al., 2022).

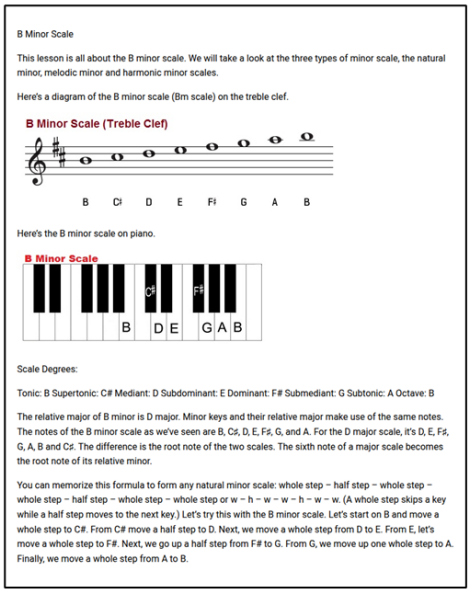
Task: *Retrieve relevant documents that help answer the question.*

Query: Determine True or False: This is the dominant in B minor. <image 1>

Answer: True

Positive Document



B Minor Scale

This lesson is all about the B minor scale. We will take a look at the three types of minor scale, the natural minor, melodic minor and harmonic minor scales.

Here's a diagram of the B minor scale (Bm scale) on the treble clef.

B Minor Scale (Treble Clef)

Here's the B minor scale on piano.

B Minor Scale

Scale Degrees:

Tonic: B Supertonic: C# Mediant: D Subdominant: E Dominant: F# Submediant: G Subtonic: A Octave: B

The relative major of B minor is D major. Minor keys and their relative major make use of the same notes. The notes of the B minor scale as we've seen are B, C♯, D, E, F♯, G, and A. For the D major scale, it's D, E, F♯, G, A, B and C♯. The difference is the root note of the two scales. The sixth note of a major scale becomes the root note of its relative minor.

You can memorize this formula to form any natural minor scale: whole step – half step – whole step – whole step – half step – whole step – whole step or w – h – w – w – h – w – w. (A whole step skips a key while a half step moves to the next key.) Let's try this with the B minor scale. Let's start on B and move a whole step to C#. From C# move a half step to D. Next, we move a whole step from D to E. From E, let's move a whole step to F#. Next, we go up a half step from F# to G. From G, we move up one whole step to A. Finally, we move a whole step from A to B.

Figure 9: Music example.

Signs and symptoms

As smaller pulmonary emboli tend to lodge in more peripheral areas without collateral circulation, th
more likely to cause lung infarction and small effusions (both of which are painful), but not hypoxia,
dyspnea, or hemodynamic instability such as tachycardia. Larger PEs, which tend to lodge centrally,
typically cause dyspnea, hypoxia, low blood pressure, fast heart rate and fainting, but are often pain
because there is no lung infarction due to collateral circulation. The classic presentation for PE with
pleuritic pain, dyspnea, and tachycardia is likely caused by a large fragmented embolism causing bi
and small PEs. Thus, small PEs are often missed because they cause pleuritic pain alone without ar
findings and large PEs are often missed because they are painless and mimic other conditions ofte
causing ECG changes and small rises in troponin and brain natriuretic peptide levels.

PEs are sometimes described as massive, submassive, and nonmassive depending on the clinical s
and symptoms. Although the exact definitions of these are unclear, an accepted definition of massiv
one in which there is hemodynamic instability. This is a cause of obstructive shock, which presents
sustained low blood pressure, slowed heart rate, or pulselessness.

Risk factors

About 90% of emboli are from a deep vein thrombosis located above the knee termed a proximal DV
which includes an iliofemoral DVT. The rare venous thoracic outlet syndrome can also be a cause of
especially in young men without significant risk factors. DVTs are at risk for dislodging and migratin
lung circulation. The conditions are generally regarded as a continuum known as a venous
thromboembolism (VTE).

VTE is much more common in immunocompromised individuals as well as individuals with comorbi
including:

- Those that undergo orthopedic surgery at or below the hip without prophylaxis.

This is due to immobility during or after the surgery, as well as venous damage during the surgery.

- Pancreatic and colon cancer patients (other forms of cancer also can be factors, but these are
most common)
- This is due to the release of procoagunts.

The risk of VTE is at its greatest during diagnosis and treatment but lowers in remission.

- Patients with high-grade tumors
- Pregnant women

Risk factors

A deep vein thrombosis as seen with signs of redness and swelling in the right leg is a risk factor for PE.

As the body puts itself into what is known as a "hypercoagulable state" the risk of a hemorrhage during childbirth is decreased and is regulated by increased expression of factors VII, VIII, X, Von Willebrand, and fibrinogen.

\blacksquare Those on estrogen medication

\blacksquare No linkage has been found to those taking progestin-only oral contraceptives.

The development of thrombosis is classically due to a group of causes named Virchow's triad (alterations in blood flow, factors in the vessel wall, and factors affecting the properties of the blood). Often, more than one risk factor is present.

\blacksquare Alterations in blood flow: immobilization (after surgery, long-haul flight), injury, pregnancy (also procoagulant), obesity (also procoagulant), cancer (also procoagulant)

\blacksquare Factors in the vessel wall: surgery, catheterizations causing direct injury ("endothelial injury")
\blacksquare Factors affecting the properties of the blood (procoagulant state)

- Estrogen-containing medication (transgender hormone therapy, menopausal hormone therapy and hormonal contraceptives)

\blacksquare Genetic thrombophilia (factor V Leiden, prothrombin mutation G20210A, protein C deficiency, protein S deficiency, antithrombin deficiency, hyperhomocysteinemia and plasminogen/fibrinolysis disorders)

\blacksquare Acquired thrombophilia (antiphospholipid syndrome, nephrotic syndrome, paroxysmal nocturnal hemoglobinuria)

Cancer (due to secretion of pro-coagulants)

Although most pulmonary embolisms are the result of proximal DVTs, there are still many other risk factors that can also result in a pulmonary embolism.

\blacksquare Risk factors include:

- Varicose veins caused by vascular damage
- Pulmonary hypertension
- Diabetes

\blacksquare Traumatic hip fractures that immobilize the patient

- Joint fixation (primarily in the legs)

Underlying causes

After a first PE, the search for secondary causes is usually brief. Only when a second PE occurs, and especially when this happens while still under anticoagulant therapy, a further search for underlying conditions is undertaken. This will include testing ("thrombophilia screen") for Factor V Leiden mutation, antiphospholipid antibodies, protein C and S and antithrombin levels, and later prothrombin mutation, MTHFR mutation, Factor VIII concentration and rarer inherited coagulation abnormalities.

Query: <image 1> With which group are leaf galls like the ones on grapevines, caused by the aphid-like insect called Grape phylloxera - which has root and leaf feeding stages in its lifecycle and is considered an extremely atypical symptom for this insect group - more commonly associated?

Answer: Mites

Positive Document

Dipteran flies

Some dipteran flies such as the cecidomyiid gall midges Dasineura investita and Neolasioptera boehmeriae, and some Agromyzidae leaf-miner flies cause galls.

Gall of *Japanagromyza inferna* (Agromyzidae) in *Centrosema virginianum*

Nettle gall caused by *Dasineura investita* (Cecidomyiidae)

False nettle stem gall caused by gall midge *Neolasioptera boehmeriae* (Cecidomyiidae)

Schizomyia impatientis (Cecidomyiidae) jewelweed flower gall

Phytoliriomyza pittosporophylli (Agromyzidae) galls in leaf of *Pittosporum undulatum*

Mites

Mites in the family Eriophyidae often cause galls to form on their hosts. The family contains more than 3,000 described species which attack a wide variety of plants.

Lime nail galls caused by the mite Eriophyes tiliae

Galls on purple coneflower caused by an undescribed mite species

Poison ivy leaf galls caused by Aculops rhois

Nematodes

Nematodes are microscopic worms that live in soil. Some nematodes (Meloidogyne species or root-knot nematodes) cause galls on the roots of susceptible plants. The galls are often small.

Southern Red Mite Damage In SHB, southern red mites primarily infest the lower side of the leaves, resulting in the accumulation of white shed skins when populations reach high numbers (Figure 3). Bronze-colored leaves are the main symptom associated with southern red mite injury, and the intensity of the bronzing is proportional to the degree of internal leaf damage (Figure 4). Like most leaf-feeding mites, the southern red mite feeds on plant tissues by inserting their mouthparts into the leaf and removing cell contents, resulting in a photosynthesis rate decline (Lopez and Liburd 2020).

Figure 3. Southern red mite shed skins. Credit: D. Phillips, UF/IFAS

Figure 4. Characteristic bronze-colored blueberry leaves associated with southern red mite damage. Credit: D. Phillips, UF/IFAS

Flat Mite or False Spider Mite Damage The characteristic symptoms associated with flat mite injury can include necrotic brown spots on leaves (Figure 5), stem browning, gall formation, brownish patches on the fruit surface, defoliation, and dieback, depending on the host plant species (Childers et al. 2003). In blueberry bushes, leaves heavily infested with flat mites often have necrotic brown spots (Figure 5). Infested leaves are sometimes infected with the bacteria Xylella sp. (Bacteria: Xanthomonadales) that causes bacterial leaf scorch disease. Irregular leaf scorch, yellow coloration, and reduced plant vigor have often been associated with flat mite or false spider mite damage (Aryazi et al. 2017). Bacterial leaf scorch, caused by Xylella fastidiosa, has been established in Florida since 2006 (Phillips et al. 2016); however, the role of flat mites in the development and spread of X. fastidiosa in Vaccinium spp. has not yet been determined.

Brevipalpus yothersi has a strong association with the citrus leprosis virus complex and it is a vector of cytoplasmic leprosis viruses (Roy et al. 2015). Blueberry necrotic ring blotch virus (BNRBV) has been reported in Florida blueberry plantings (Phillips et al. 2018), and it is closely related to these viruses. BNRBV induces localized necrotic or chlorotic lesions like the characteristic symptoms associated with B. yothersi feeding. However, the potential role of false spider mites or flat mites as a vector of BNRBV is unknown.

Query: In 1946, the person in <image 1> was arrested for refusing to sit in the blacks-only section of the cinema in Nova Scotia. This is an example of_____.

Answer: A conflict crime

Positive Document

Conflict criminology

Largely based on the writings of Karl Marx, conflict criminology holds that crime in capitalist societies cannot be adequately understood without a recognition that such societies are dominated by a wealthy elite whose continuing dominance requires the economic exploitation of others, and that the ideas, institutions and practices of such societies are designed and managed in order to ensure that such groups remain marginalised, oppressed and vulnerable. Members of marginalised and oppressed groups may sometimes turn to crime in order to gain the material wealth that apparently brings equality in capitalist societies, or simply in order to survive. Conflict criminology derives its name from the fact that theorists within the area believe that there is no consensual social contract between state and citizen.

Discussion

Conflict theory assumes that every society is subjected to a process of continuous change and that this process creates social conflicts. Hence, social change and social conflict are ubiquitous. Individuals and social classes, each with distinctive interests, represent the constituent elements of a society. As such, they are individually and collectively participants in this process but there is no guarantee that the interests of each class will coincide. Indeed, the lack of common ground is likely to bring them into conflict with each other. From time to time, each element's contribution may be positive or negative, constructive or destructive. To that extent, therefore, the progress made by each society as a whole is limited by the acts and omissions of some of its members by others. This limitation may promote a struggle for greater progress but, if the less progressive group has access to the coercive power of law, it may entrench inequality and oppress those deemed less equal. In turn, this inequality will become a significant source of conflict. The theory identifies the state and the law as instruments of oppression used by the ruling class for their own benefit.

There are various strands of conflict theory, with many heavily critiquing the others. Structural Marxist criminology, which is essentially the most 'pure' version of the above, has been frequently accused of idealism, and many critics point to the fact that the Soviet Union and such states had as high crime rates as the capitalist West. Furthermore, some highly capitalist states such as Switzerland have very low crime rates, thus making structural theory seem improbable.

Area of Sector

Tags: Circles, Geometry, Area of Sector, Area Formulas

Theorem
Let $\mathcal{C} = ABC$ be a circle whose center is A and with radii AB and AC.
Let BAC be the sector of $\mathcal{C}$ whose angle between AB and AC is θ.

Then the area $\mathcal{A}$ of sector BAC is given by:

$$\mathcal{A} = \frac{r^2\theta}{2} \tag{1}$$

where:

- $r = AB$ is the length of the radius of the circle,
- θ is measured in radians.

Proof

> ***Note**: To be replaced with something rigorous, based on calculus.*

From *Area of Circle*, the area of $\mathcal{C}$ is πr^2.
From *Full Angle measures* 2π *Radians*, the angle within $\mathcal{C}$ is 2π.
The fraction of the area of $\mathcal{C}$ within the sector BAC is therefore:

$$\pi r^2 \times \frac{\theta}{2\pi} \tag{2}$$

Hence the result.

Area of Circle

Tags: Circles, Area of Circle, Euclidean Geometry, Area Formulas

Theorem
The area A of a circle is given by:

$$A = \pi r^2 \tag{1}$$

where r is the radius of the circle.

Proof

We start with the equation of a circle:

$$x^2 + y^2 = r^2 \tag{2}$$

Thus $y = \pm\sqrt{r^2 - x^2}$. From the geometric interpretation of the definite integral, the area A is:

$$\begin{aligned} A &= \int_{-r}^{r} \left[\sqrt{r^2 - x^2} - \left(-\sqrt{r^2 - x^2}\right)\right] dx \\ &= \int_{-r}^{r} 2\sqrt{r^2 - x^2}\, dx \\ &= \int_{-r}^{r} 2r\sqrt{1 - \frac{x^2}{r^2}}\, dx \end{aligned} \tag{3}$$

Let $x = r\sin\theta$ (note that this substitution is valid because $-r \le x \le r$).
Then $\theta = \arcsin\left(\frac{x}{r}\right)$ and $dx = r\cos\theta\, d\theta$.

Applying integration by substitution:

$$\begin{aligned} A &= \int_{\arcsin(-1)}^{\arcsin(1)} 2r^2\sqrt{1 - \frac{(r\sin\theta)^2}{r^2}}\cos\theta\, d\theta \\ &= \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} 2r^2\sqrt{1 - \sin^2\theta}\cos\theta\, d\theta \\ &= \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} 2r^2\sqrt{\cos^2\theta}\cos\theta\, d\theta \\ &= r^2\left[\theta + \frac{1}{2}\sin(2\theta)\right]_{-\frac{\pi}{2}}^{\frac{\pi}{2}} \\ &= \pi r^2 \end{aligned} \tag{4}$$

Speed

Definition

The **speed** of a body is a measure of the magnitude of its velocity, independent of direction.

Because it disregards direction, speed is a **scalar quantity**.

Mathematically, if $\mathbf{v}$ is the velocity vector of a body, then its speed s is given by:

$$s = \|\mathbf{v}\|$$

where $\|\cdot\|$ denotes the magnitude (or norm) of the vector.

Current in Electric Ci
L, R, C in Series

Tags: Electronics

Theorem
Consider the electrical circuit K consist

- a resistance R,
- an inductance L,
- a capacitance C,

connected in series with a source of elec
force $E(t)$, which is a function of time t

The electric current $I(t)$ in K satisfies t
second-order ordinary differential equa

$$L\frac{d^2I}{dt^2} + R\frac{dI}{dt} + \frac{1}{C}I = \frac{d}{d}$$

Proof

Let:

- E_L be the voltage drop across the inductor L,
- E_R be the voltage drop across the resistor R,
- E_C be the voltage drop across the capacitor C.

By **Kirchhoff's Voltage Law**, the sum of voltage drops equals the applied EMF:

$$E - E_L - E_R - E_C = 0 \tag{2}$$

Using fundamental circuit laws:

- **Ohm's Law**: $E_R = RI$,
- **Inductor voltage**: $E_L = L\frac{dI}{dt}$,
- **Capacitor voltage**: $E_C = \frac{1}{C}Q$, where $Q(t)$ is the charge on the capacitor.

Substituting these into Kirchhoff's law:

$$E - L\frac{dI}{dt} - RI - \frac{1}{C}Q = 0 \tag{3}$$

Rearranging:

$$L\frac{dI}{dt} + RI + \frac{1}{C}Q = E \tag{4}$$

Recall that current is the time derivative of charge: $I = \frac{dQ}{dt}$.
Differentiating both sides of the equation with respect to t:

$$L\frac{d^2I}{dt^2} + R\frac{dI}{dt} + \frac{1}{C}\frac{dQ}{dt} = \frac{dE}{dt} \tag{5}$$

Since $\frac{dQ}{dt} = I$, we obtain:

$$L\frac{d^2I}{dt^2} + R\frac{dI}{dt} + \frac{1}{C}I = \frac{dE}{dt} \tag{6}$$

\SpendingMultiplierFormula

The Spending Multiplier Formula in macroeconomics measures the ratio of the change in aggregate demand or Gross Domestic Product to an initial change in spending, typically government expenditure. It quantifies the cumulative effect on national income when there is an increase or decrease in autonomous spending.

Mathematically, the spending multiplier is expressed as:

$$\text{Spending Multiplier} = \frac{1}{1 - MPC}$$

where MPC is the marginal propensit
rather than save.

Alternatively, since MPS $marginalpr$

\textbf{Example:}
If $MPC = 0.8$,, then:

This means that an initial increase in

Multiplier Effect on GDP

Definition

The **multiplier effect on GDP** refers to the phenomenon whereby an initial change in aggregate demand—such as through government spending, tax cuts, or investment—causes a proportionally larger change in aggregate output (Gross Domestic Product) and income.

This occurs because the initial spending generates income for recipients (e.g., wages to workers, payments to suppliers), who in turn spend a fraction of that income according to their **marginal propensity to consume (MPC)**. That subsequent spending becomes income for others, who also spend a portion, and so on. This repeated cycle of spending and re-spending can result in the total increase in GDP being a multiple of the initial increase in spending.

Mathematical Representation

The size of the multiplier depends on several key economic parameters. A general form of the fiscal multiplier accounting for taxes and imports is:

$$\Delta y = \Delta G \cdot \frac{1}{1 - b_C(1 - b_T) + \lambda_M} \quad (1)$$

where:

- Δy = change in GDP
- ΔG = change in government spending
- b_C = marginal propensity to consume (MP
- b_T = income tax rate
- b_M = marginal propensity to import (MPI

In the simplest case—**without taxes or imports**—t

where k is the fiscal multiplier.

Marginal Propensity to Save Relationship

Definition

The value Keynes assigns to his multiplier is the reciprocal of the marginal propensity to save: $k = \frac{1}{1-b}$

This is the same as the formula for Kahn's multiplier in a closed economy assuming that all saving (including the purchase of durable goods), and not just hoarding, constitutes leakage. Keynes gave his formula almost the status of a definition (it is put forward in advance of any explanation). His multiplier is indeed the value of 'the ratio ... between an increment of investment and the corresponding increment of aggregate income' as Keynes derived it from his Chapter 13 model of liquidity preference, which implies that income must bear the entire effect of a change in investment. But under his Chapter 15 model a change in the schedule of the marginal efficiency of capital has an effect shared between the interest rate and income in proportions depending on the partial derivatives of the liquidity preference function. Keynes did not investigate the question of whether his formula for multiplier needed revision. \end{definition}
